Template Books

C++ Templates: The Complete Guide (2nd)

D. Vandevoorde, N. M. Josuttis, D. Gregor, 2017

Function Template

Template Overview

Template

A **template** is a mechanism for generic programming to provide a "schema" (or placeholders) to represent the structure of an entity

In C++, templates are a compile-time functionality to represent:

- A family of **functions**
- A family of classes
- A family of **variables** C++14

The problem: We want to define a function to handle different types

```
int add(int a, int b) {
   return a + b;
}
float add(float a, float b) { // overloading
    return a + b;
      add(char a, char b) { ... } // overloading
char
ClassX add(ClassX a, ClassX b) { ... } // overloading
```

- Redundant code!!
- How many functions we have to write!?
- If the user introduces a new type we have to write another function!!

Function Template

A **function template** is a function schema that operates with *generic* types (independent of any particular type) or concrete values

A function template works with multiple types without repeating the entire code for each of them

```
template<typename T> // or template<class T>
T add(T a, T b) {
    return a + b;
}
int c1 = add(3, 4);  // c1 = 7
float c2 = add(3.0f, 4.0f); // c2 = 7.0f
```

Templates: Benefits and Drawbacks

Benefits

- Generic Programming: Less code and reusable. Reduce redundancy, better maintainability and flexibility
- ullet Performance. Computation can be done/optimized at compile-time o faster

Drawbacks

- Readability. "With respect to C++, the syntax and idioms of templates are
 esoteric compared to conventional C++ programming, and templates can be very
 difficult to understand" [wikipedia] → hard to read, cryptic error messages
- Compile Time/Binary Size. Templates are implicitly instantiated for every distinct parameters

Template Instantiation

Template Instantiation

The **template instantiation** is the substitution of template parameters with concrete values or types

The compiler *automatically* generates a **function implementation** for <u>each</u> template instantiation

```
template<typename T>
T add(T a, T b) {
    return a + b;
}
add(3, 4);  // generates: int add(int, int)
add(3.0f, 4.0f); // generates: float add(float, float)
add(2, 6);  // already generated
// other instances are not generated
// e.g. char add(char, char)
9/47
```

Implicit and Explicit Template Instantiation

Implicit Template Instantiation

Implicit template instantiation occurs when the compiler generates code depending on the *deduced argument types* or the *explicit template arguments* and only when the definition is needed

Explicit Template Instantiation

Explicit template instantiation occurs when the compiler generates code depending only on the *explicit template arguments* specified in the <u>declaration</u>. Useful when dealing with multiple translation units to reduce the binary size

Implicit and Explicit Template Instantiation

Template Parameters

Template Parameters

Template Parameters are the names following the template keyword

```
template<typename T>
void f() {}

f<int>();
```

typename T is the template parameter

int is the template argument

A **template parameter** can be a *generic type*, i.e. typename, as well as a *non-type template parameters* (NTTP), e.g. int, enum, etc.

The **template argument** of a *generic type* is a built-in or user-declared type, while a concrete value for a *non-type template parameter*12/47

int parameter

```
template<int A, int B>
int add_int() {
   return A + B; // sum is computed at compile-time
} // e.g. add_int<3, 4>();
```

enum parameter

```
enum class Enum { Left, Right };

template<Enum Z>
int add_enum(int a, int b) {
   return (Z == Enum::Left) ? a + b : a;
}  // e.g. add_enum<Enum::Left>(3, 4);
```

Ceiling division

```
template<int DIV, typename T>
T ceil_div(T value) {
    return (value + DIV - 1) / DIV;
}
// e.g. ceil_div<5>(11); // returns 3
```

Rounded division

```
template<int DIV, typename T>
T round_div(T value) {
   return (value + DIV / 2) / DIV;
}
// e.g. round_div<5>(11); // returns 2 (2.2)
```

Since DIV is known at compile-time, the compiler can heavily optimize the division (almost for every number, not just for power of two)

C++11 Template parameters can have default values

```
template<int A = 3, int B = 4>
void print1() { cout << A << ", " << B; }</pre>
template<int A = 3, int B> // still possible, but little sense
void print2() { cout << A << ". " << B: }</pre>
print1<2, 5>(); // print 2, 5
print1<2>();  // print 2, 4 (B: default)
print1<>();  // print 3, 4 (A,B: default)
print1(); // print 3, 4 (A,B: default)
print2<2, 5>(); // print 2, 5
// print2<2>(); compile error
// print2<>(); compile error
// print2(); compile error
```

Template parameters may have no name

```
void f() {}

template<typename = void>
void g() {}

int main() {
    g(); // generated
}
```

f() is <u>always</u> generated in the final codeg() is generated in the final code only if it is called

$\mathsf{C}++11$ Unlike function parameters, template parameters can be initialized by previous values

```
template<int A, int B = A + 3>
void f() {
   cout << B:
template<typename T, int S = sizeof(T)>
void g(T) {
   cout << S:
f<3>(); // B is 6
g(3); // S is 4
```

Function Template Overloading

Template Functions can be *overloaded*

Concrete type overloading has higher precedence

Also, templates themselves can be overloaded

Template Specialization

Template specialization refers to the concrete implementation for a specific combination of template parameters

The problem:

```
template<typename T>
bool compare(T a, T b) {
   return a < b;
}</pre>
```

The direct comparison between two floating-point values is dangerous due to rounding errors

Solution: Template specialization

```
template<>
bool compare<float>(float a, float b) {
    return ... // a better floating point implementation
}
```

Template Variable

Template Variable

C++14 allows variables with templates

A template variable can be considered a special case of a *class template* (see next lecture)

```
template<typename T>
constexpr T pi{ 3.1415926535897932385 }; // variable template
template<typename T>
T circular area(T r) {
    return pi<T> * r * r; // pi<T> is a variable template instantiation
circular_area(3.3f); // float
circular area(3.3); // double
// circular area(3); // compile error, narrowing conversion with "pi"
```

Template Parameter

Types

Template Parameter Types

Template parameters can be:

- integral type
- enum, enum class
- floating-point type C++20
- auto placeholder C++17
- class literals and concepts C++20
- generic type typename

and rarely:

- function
- reference/pointer to global static function or object
- pointer to member type
- nullptr_t C++14

Generic Type Notes

Pass multiple values and floating-point types

```
template<float V> // only in C++20
void print_float() {}
template<tvpename T>
void print() {
    cout << T::x << ", " << T::y;
struct Multi {
    static const int x = 1:
    static constexpr float y = 2.0f;
};
print<Multi>(); // print "1, 2"
```

auto Placeholder

C++17 introduces automatic deduction of *non-type* template parameters with the auto keyword

```
template<int X, int Y>
void f() {}
template<typename T1, T1 X, typename T2, T2 Y>
void g1() {} // before C++17
template<auto X, auto Y>
void g2() {}
f<2u, 2u>(); // X: int, Y: int
g1<int, 2, char, 'a'>(); // X: int, Y: char
g2<2, 'a'>(); // X: int, Y: char
```

Function

```
template<int (*F)(int, int)> // <-- signature of "f"</pre>
int apply1(int a, int b) {
   return F(a, b);
int f(int a, int b) { return a + b; }
int g(int a, int b) { return a * b; }
template<decltype(f) F> // alternative syntax
int apply2(int a, int b) {
    return F(a, b):
int main() {
    apply1<f>(2, 3); // return 5
    apply2<g>(2, 3); // return 6
```

Compile-Time

Utilities

$C++11\ \mathtt{static_assert}$ is used to test an assertion at $\underline{\mathtt{compile-time}},\ \mathtt{e.g.}$

sizeof , literals, templates, constexpr

If the static assertion fails, the program does not compile

```
static_assert(2 + 2 == 4, "test1"); // ok, it compiles
static_assert(2 + 2 == 5, "test2"); // compile error, print "test2"
```

C++17: assertions without messages

```
template<typename T, typename R>
void f() { static_assert(sizeof(T) == sizeof(R)); }

f<int, unsigned>(); // ok, it compiles
// f<int, char>(); // compile error
```

C++26: assertions with text formatting

```
static_assert(sizeof(T) != 4, std::format("test1 with sizeof(T)={}", sizeof(T))); 26/47
```

using keyword (C++11)

The using keyword introduces an alias-declaration or alias-template

- using is an enhanced version of typedef with a more readable syntax
- using can be combined with templates, as opposite to typedef
- using is useful to simplify complex template expression
- using allows introducing new names for partial and full specializations

```
typedef int distance_t; // equal to:
using distance_t = int;

typedef void (*function)(int, float); // equal to:
using function = void (*)(int, float);
```

Full/Partial specialization alias:

Accessing a type within a structure:

```
struct A {
    using type = int;
};
using Alias = A::type;
```

C++11 decltype keyword deduces the type of an *entity* or *expression*

- decltype is always evaluated at compile-type
- decltype(entity) returns the declared type of the entity
- decltype(expression) returns the type of the expression
 - A variable evaluated as an expression, i.e. decltype((var)), is deduced as an Ivalue
 - $\tt a$ A general expression, e.g. decltype((a + b)), is deduced as its final type

```
int x = 3;
int & y = x;
const int z = 4;
int array[2];
void f(int, float);
decltype(x); // int
decltype(2 + 3.0); // double
decltype(v): // int&
decltype(z); // const int
decltype(array); // int[2]
decltype(f(1, 2.0f)); // void, i.e. the return type of 'f'
decltype(f); // void (int, float), i.e. the signature of 'f'
decltype(x) y = 3; // 'y' is int
using T = y; //T is int&
```

```
bool f(int);
struct A {
   int x;
};
int x = 3;
const A a{4};
decltype(x) d1; // int
decltype((x)) d2 = x; // int&
decltype(f) d3; // bool (int)
decltype((f)) d4 = f; // bool (&)(int)
decltype(a.x) d5; // int
decltype((a.x)) d6 = x; // const int&
```

C + +11

```
template<typename T, typename R>
decltype(T{} + R{}) add(T x, R y) {
    return x + y;
}
unsigned v1 = add(1, 2u);
double v2 = add(1.5, 2u);
```

C++14

```
template<typename T, typename R>
auto add(T x, R y) {
    return x + y;
}
```

Type Traits

Introspection

Introspection is the ability to inspect a type and query its properties

Reflection

Reflection is the ability of a computer program to examine, introspect, and <u>modify</u> its own structure and behavior

C++ provides $\underline{compile\text{-time}}$ reflection and introspection capabilities through \underline{type} \underline{traits}

Type traits (C++11)

Type traits define a <u>compile-time</u> interface to *query* or *modify* the properties of types

The problem:

```
template<typename T>
T integral_div(T a, T b) {
    return a / b;
}
integral_div(7, 2);  // returns 3 (int)
integral_div(71, 21);  // returns 3 (long int)
integral_div(7.0, 3.0); // !!! a floating-point value is not an integral type
```

Two alternatives: (1) Specialize (2) Type Traits + static_assert

. . .

If we want to prevent floating-point/other objects division at compile-time, a first solution consists in specialize for all integral types

```
template<typename T>
T integral_div(T a, T b); // declaration (error for other types)
template<>
char integral_div<char>(char a, char b) { // specialization
   return a / b;
template<>
int integral div<int>(int a, int b) {  // specialization
    return a / b;
...unsigned char
...short
```

The best solution is to use type traits

value is true if T is bool, char, short, int, long, long long, false otherwise

C++17 provides utilities to improve the readability of type traits

```
std::is_integral_v<T>; // std::is_integral<T>::value
```

```
short, int, long, etc.)
• is floating point checks for a floating-point type (float, double)
```

is integral checks for an integral type (bool, char, unsigned char,

- is arithmetic checks for a integral or floating-point type
- is signed checks for a signed type (float, int, etc.)
- is unsigned checks for an unsigned type (unsigned, bool, etc.) is enum checks for an enumerator type (enum, enum class)

is null pointer checks for a (nullptr) C++14

- is void checks for (void)
- is_pointer checks for a pointer (T*)

37/47

Entity type queries:

- is_reference checks for a reference (T&)
- is_array checks for an array (T (&) [N])
- is_function checks for a function type

Class queries:

- is_class checks for a class type (struct , class)
- is_abstract checks for a class with at least one pure virtual function
- is_polymorphic checks for a class with at least one virtual function

Type property queries:

• is_const checks if a type is const

Type relation:

- is_same<T, R> checks if T and R are the same type
- is_base_of<T, R> checks if T is base of R
- is_convertible<T, R> checks if T can be converted to R

39/47

Example - const **Deduction**

```
#include <type traits>
template<typename T>
void f(T x) { cout << std::is_const_v<T>; }
template<typename T>
void g(T& x) { cout << std::is const v<T>; }
const int a = 3;
f(a); // print false, "const" drop in pass by-value
g(a); // print true
const int* b = nullptr;
g(b); // print false!! T: (const int)*, 'b' can be modified by 'q()'
int* const c = nullptr;
g(c); // print true!! T: const (int*), 'c' cannot be modified by 'q()'
```

Example - Type Relation

```
#include <type_traits>
template<typename T, typename R>
T add(T a, R b) {
    static_assert(std::is_same_v<T, R>, "T and R must have the same type");
    return a + b;
}
add(1, 2);  // ok
// add(1, 2.0); // compile error, "T and R must have the same type"
```

```
#include <type_traits>
struct A {};
struct B : A {};

std::is_base_of_v<A, B>;  // true
std::is_convertible_v<int, float>; // true
```

Type Manipulation

Type traits allow also to manipulate types by using the type field

Example: produce unsigned from int

C++14 provides utilities to improve the readability of type traits

```
std::make_unsigned_t<T>; // instead of 'typename std::make_unsigned<T>::type'
```

Signed and Unsigned types:

- make_signed makes a signed type
- make_unsigned makes an unsigned type

Pointers and References:

- remove_pointer remove pointer (T* \rightarrow T)
- remove_reference remove reference (T& \rightarrow T)
- add_pointer add pointer (T → T*)
- lacktriangledown add_lvalue_reference add reference (T ightarrow T&)

const specifiers:

- lacktriangledown remove const (const T ightarrow T)
- add_const add const

Other type transformation:

- common_type<T, R> returns the common type between T and R
- conditional<pred, T, R> returns T if pred is true, R otherwise
- decay<T> returns the same type as a function parameter passed by-value

Type Manipulation Example

```
#include <type traits>
template<typename T>
void f(T ptr) {
    using R = std::remove_pointer_t<T>;
   R x = ptr[0]; // char
template<typename T>
void g(T x) {
    using R = std::add_const_t<T>;
   R v = 3:
// y = 4; // compile error
char a[] = "abc";
f(a): // T: char*
g(3); // T: int
```

std::common_type Example

```
#include <type traits>
template<typename T, typename R>
std::common_type_t<R, T> // <-- return type
add(T a, R b) {
   return a + b;
// we can also use decltype to derive the result type
using result_t = decltype(add(3, 4.0f));
result_t x = add(3, 4.0f);
```

std::conditional Example

```
#include <type traits>
template<typename T, typename R>
auto f(T a, R b) {
    constexpr bool pred = sizeof(T) > sizeof(R);
    using S = std::conditional_t<pred, T, R>;
    return static_cast<S>(a) + static_cast<S>(b);
f( 2, 'a'); // return 'int'
f( 2, 2ull); // return 'unsigned long long'
f(2.0f, 2ull); // return 'unsigned long long'
```
